WHAT WE DON’T KNOW CAN HURT US

Pilot Prevalence Survey of Incontinence and Related Perineal Skin Injury in Acute Care

Joan Junkin, MSN, RN, CWOCN, BryanLGH Medical Center • Gayle Moore-Lisi, RN, MSN, CWOCN, University Hospitals of Cleveland • Joan Lerner Seleko, BSN, RN, CWOCN, University of Maryland Medical Center

ABSTRACT

Incontinence is associated with increased use of healthcare dollars for caregiver time, containment, cleansing and skin protection products, and skin injuries. The injuries associated with incontinence, such as pressure ulcers, dermatitis and secondary infections, are considered preventable and viewed as quality indicators by regulators and consumers. Although well-defined in long term care, there is a gap in reporting for acute care. Three medical centers conducted a pilot prevalence survey of incontinence and perineal skin injury in March of 2005.

Total patient census was 1,004 with complete data present for 976 with an equal mix of male and female. Foley catheters were present in 341 (34.9%) patients (considered continent). 198 (20.3%) were incontinent of urine (2.6%), stool (13%) or both (4.7%) in the preceding 24 hours. Of the patients with incontinence, 54% (106/198) had a skin injury of the perineal area. 33% had a pressure ulcer, 27% perineal dermatitis, and 18% fungal infection. Of those patients, 21% (42/198) had more than one type of injury. Skin injury was more prevalent (93%, 99/106) for incontinent patients with containment products than those without (7%, 8/106).

This pilot survey is among the first to define the prevalence of incontinence and perineal skin injury in acute care. Clearly, incontinence with fecal involvement is prevalent. Issues identified as a result of this survey include: the need for operational definitions for perineal dermatitis as differentiated from pressure ulcers, identification of risk factors, and exploration of the role that containment and protective products play.

Behavioral Objectives:
1. Participant will be able to identify the extent of incontinence in the acute care setting.
2. Participant will be able to list three types of perineal skin injury related to incontinence.
3. Participant will be able to discuss trends for incontinence and perineal skin injury in acute care.
INTRODUCTION

Increased emphasis from regulating agencies on the prevention of nosocomial pressure ulcers in healthcare institutions today requires us to better understand our hospital patient population and the etiology of their skin injuries. Incontinence has long been associated as a risk factor for pressure ulcer development; however, other skin injuries associated with incontinence remain in the background.

The objective of this pilot survey was to identify the prevalence of incontinence in acute care, the frequency of skin injury in the incontinent patient, and current care practices in the management of incontinent patients.

Three medical centers agreed to participate in a pilot prevalence survey of incontinence and perineal skin injury.

The coordination of the data collection occurred through the Wound, Ostomy and Continence nurses at each institution today requires us to better understand our hospital patient population and the etiology of their skin injuries. Incontinence has long been associated as a risk factor for pressure ulcer development; however, other skin injuries associated with incontinence remain in the background.

The pilot survey was conducted at three geographically diverse acute care hospitals in the spring of 2005. Adult acute care inpatients including critical care, medical, and surgical diagnosis were the intended target population of this survey with the universal exclusion of Labor & Delivery and Neonatal patients.

University of Maryland Medical Center (UMMC) is a 650-bed academic medical center that is part of a six-hospital system. Three pediatric patients (4-19 yrs) were included on surveyed units at UMMC. Units excluded were Psychiatric and Rehabilitation.

University Hospitals of Cleveland (UHHS) is a 947-bed tertiary medical center specializing in adult/geriatric medical and surgical specialties. Units excluded were Psychiatric, Long Term Rehabilitation and Skilled Nursing.

BryanLGH consists of two acute care facilities in Lincoln, Nebraska with 500 beds that serve the midwest region. Geriatric Psych and Rehabilitation units were included in data collection.

UHHS and BryanLGH coordinated the pilot survey to coincide with a routine site pressure ulcer prevalence survey.

DEFINITIONS

A requirement of the data collectors was the ability to differentiate perinatal skin injury between pressure ulcers, perineal dermatitis, fungal infections, and other injuries. Skin injury was more prevalent (92%, 92/106) in patients placed on containment products than those who were not (8%, 8/106).

Although research supports the efficacy of polymer core/air flow pads and briefs in better patient skin outcomes, the most frequent containment devices for absorbtion were cloth pads, plastic-backed pads and diaper/briefs. This survey prompted all three pilot sites to re-evaluate containment product choices in their facilities and implement changes as necessary.

Revealingly, 40% of incontinent patients had multiple containment products used, the most frequent being a cloth pad, plastic-backed pad or both used in combination with a brief. This practice, however, was not necessarily tied to any specific type of incontinence. It is also reflective of the multiple choices available for cleanup and skin protection products that could lead to confusion and inconsistency in product selection.

CONCLUSION

This pilot survey is among the first to define the prevalence of incontinence and perineal skin injury in acute care. Clearly, incontinence with fecal prevalence of incontinence and perineal skin injury in acute care. Clearly, incontinence with fecal
